Combining Thm.2.1 with the results of Chapter B-III one can describe the behavior of T(t) as $t \to \infty$ provided that $(T(t))_{t \ge 0}$ is a positive semigroup. We give a typical example.

Corollary 2.2. Let $(T(t))_{t \geq 0}$ be a positive semigroup on a space $C_0(X)$ which is irreducible and eventually compact. Then there exist a unique real number $r \in \mathbb{R}$, a strictly positive function h and a strictly positive bounded Borel measure v such that for suitable constants $\delta > 0$, $M \geq 1$ one has

(2.2) $\|\exp(-rt) \cdot T(t) - v_{\theta}h\| \leq M \cdot e^{-\delta t}$ for all $t \geq 0$.

In particular, for every $f \in C_0(X)$ and $t \ge 0$ one has

(2.3)
$$e^{rt}(|\int f dv| - M \cdot e^{-\delta t} ||f||) \le ||T(t)f|| \le e^{rt}(|\int f dv| + M \cdot e^{-\delta t} ||f||)$$
.

<u>Proof.</u> We take r := s(A). By B-III, Prop. 3.5 (a) we have $r > -\infty$. Moreover, by assertion (e) of the same proposition we know that r is an algebraically simple pole and the corresponding residue P has the form $P = v \otimes h$ for strictly positive eigenvectors v and h of A and A', respectively. Without loss of generality we may assume $\|h\| = 1$. Corollary 2.11 of Chapter B-III implies that r is strictly dominant, i.e., enumerating the eigenvalues as described in Thm.2.1 we have $Re \lambda_2 < \lambda_1 = r$. Now (2.2) follows from (2.1) for m = 1.
